ISSN 0004-5411 (print), 1557-735X (electronic). URL http://www.acm.org/pubs/toc/Abstracts/0004-5411/102783.html. A constant time oracle is assumed for determining if a point in space is inside or outside a convex body in $n$-dimensional Euclidean space. The algorithm runs in time bounded by a polynomial in $n$, the dimension of the body, and $1/\epsilon$, where $\epsilon$ is the relative error bound. With probability $3/4$, it finds an approximation satisfying the error bound.

This paper proves that every completely asynchronous, deterministic algorithm for Byzantine agreement has the possibility of nontermination, even with only one faulty processor. This impossibility result does not hold in the synchronous case. For completely asynchronous probabilistic algorithms, the problem is avoided since termination is only required with probability 1. See Section xxx for an example of such a probabilistic algorithm for asynchronous Byzantine agreement.

ISSN 0004-5411 (print), 1557-735X (electronic). They study the complexity of deciding the equivalence of straight-line programs, i.e., those in which there are no loops, and only statements of the form $x := y$, $x := y + z$, $x := y - z$, and $x := y * z$ are permitted. Given two such programs $P$ and $Q$, Ibarra and Moran ask the question: Is $P = Q$? If the domain of the variables is an infinite field such as the integers, then they show that there exists a polynomial-time probabilistic algorithm to solve this problem. If the domain is a finite field, the problem is shown to be $NP$-hard.

Michael Kaminski. A note on probabilistically verifying integer and polynomial products. *Journal of the ACM*, 36(1):142–149, January 1989. CODEN JACOAH. ISSN 0004-5411 (print), 1557-735X (electronic). URL http://www.acm.org/pubs/toc/Abstracts/0004-5411/214082.html. The author describes probabilistic algorithms for verifying the product of two $n$-bit integers in $O(n)$ bit operations, and for verifying the product of two polynomials of degree $n$ over integral domains in $4n + o(n)$ algebraic operations. The error probability is $o\left(\frac{1}{n^{1+\epsilon}}\right)$ for any $\epsilon > 0$.

This paper compares lower bounds on the running times of algorithms that allow probabilistic, non-deterministic and alternating control on decision trees. Decision trees that allow internal randomization at the expense of a small probability of error are shown to run no faster asymptotically than ordinary decision trees for a collection of problems. An earlier version of this publication appeared in Proc. 14th Ann. ACM Symp. on Theory of Computing, 1982, pp. 234–244.

URL http://www.acm.org/pubs/toc/Abstracts/0004-5411/62053.html. Inductive inference machines construct total recursive functions \( \phi(x) \) given examples of the input and output of \( \phi \). Probabilistic inductive inference machines are permitted coin tosses while constructing \( \phi \), and are only required to construct \( \phi \) with probability \( p \), \( 0 < p < 1 \). This paper shows a discrete hierarchy of inferability parameterized by \( p \), for \( p \leq 1/2 \). Any machine that can be constructed by probabilistic inference with \( p > 1/2 \) can also be constructed deterministically.

This paper is similar to their 1982 publication [LSP82], but contains a rigorous proof of the impossibility of Byzantine agreement for the case \( n = 3, t = 1 \). As usual, \( n \) is the total number of processes and \( t \) is the number of faulty processes.

Rackoff attempts to prove $R \neq P$ by assuming $P \neq NP$ and relativization (i.e., for a class of languages $C$, $C^A$ is the same as $C$ except that one can answer questions concerning membership in $A$ in constant time). Interestingly, he proves that for some oracle $A$, $P^A \neq NP^A$ and $R^A \neq P^A$, and at the same time, for some other oracle $B$, $P^B \neq NP^B$ and $R^B \neq P^B$.
