According to Knuth [Knu73, p. 507], this is one of two papers that first discuss the birthday paradox: “if 23 or more people are present in the same room, chances are good that two of them will have the same month and day of birth! In other words, if we select a random function which maps 23 keys into a table of size 365, the probability that no two keys map into the same location is only 0.4927 (less than one-half).” The discovery is credited to unpublished work of H. Davenport (1927). See also [vM39].

The design and security of block ciphers, together with their application in hashing techniques, are considered. In particular, iterated block ciphers that are based on iterating a weak round function several times

are considered. Four basic constructions for the round function of an iterated cipher are studied.” [Lan06]
